AIR CONDITIONING SYSTEMS COMFORT GUIDE

WALL SPLIT SYSTEM

A WALL Split System is a popular way to cool/heat a single room or open living area. It consists of an indoor Cooling/Heating unit (or evaporator) mounted on an indoor wall and an Outdoor unit (or a Condenser) located at the side of the building, which contains the compressor motor that generates cooling and heating as required. Split systems are very effective at cooling/heating the room or space that the indoor unit is mounted in, and they come with a remote control that allows you to select desired temperature and other functions such as airflow direction strength, heat, cool, dry, fan, etc.

If the indoor unit is mounted in the Loungeroom, for example, you could expect quite effective cooling or heating of the Loungeroom area, however; cooling or heating to **other rooms** in the house is usually limited.

There are a wide range of Wall Split Systems available, for best results we use and recommend **LG, DAIKIN** and **HITACHI**.

Split System features;

- Quiet
- Cost Effective
- Energy Efficient
- **Average cost of a split system fully installed is usually around \$2-3,000** for most home situations (depending on the size of the system and installation considerations)

Limitations;

- Requires a visible indoor unit on the wall
- Cannot condition other rooms, only the room the indoor unit is positioned in
- Cannot be extended to condition other rooms at a later date

DUCTED SYSTEM

A DUCTED System is usually the best way to Heat/Cool **multiple rooms**.

It consists of an indoor Cooling/Heating unit (or evaporator) mounted out of sight in the ceiling space, and an Outdoor unit (or Condenser) located outside of the building (the outside unit contains the compressor motor that generates cooling and heating as required). Insulated Flexible tubing (or ducting) connects the indoor Cooling/Heating unit (or evaporator) to the air conditioned rooms via vents located in the ceiling. The ducted indoor unit is located in the ceiling space.

Ducted systems are **effective at cooling multiple rooms**, and can also be switched between groups of rooms (or zones) as required. Switching between areas (or zones) of the home that are used during the day such as living areas, and areas (or zones) of the home that are used during the night, Bedrooms for example.

The Ducted system comes with a central wall mounted control that allows you to select desired temperature and other functions such as airflow strength, areas to be conditioned etc. With ceiling vents in each conditioned room; cooling or heating to all of the selected areas of the house is achieved.

There are a wide range of Ducted Systems available, for best results we use and recommend **DAIKIN** and **HITACHI**.

Split DUCTED System features;

- Quiet
- Cost Effective for multiple rooms
- Energy Efficient
- CAN condition Multiple rooms at once
- Can be extended to other rooms at a later date
- Can be switched between groups of rooms (or zones) eg. Day areas and night areas
- No visible indoor unit on the wall
- **Average cost of a ducted system fully installed is usually around \$10-14,000** for most home situations (depending on the size of the system, number of areas or zones, and any other installation considerations)

Limitations;

- Initial investment cost of the system is higher than a single Wall Split System

RUNNING COSTS;

Inverters are the most energy efficient Air Conditioning units on the market today.

Utilising Inverter technology as well as other power saving features, modern air conditioners have greatly minimised the electrical costs associated with running an Air Conditioner (compared to non-inverter types).

Having said that, there are obviously some costs associated with running even an Inverter Air Conditioner.

Did you know? Running your AC even one degree cooler on HEATING (say 20 degrees instead of 21 degrees) or one degree higher on COOLING (say 23 degrees instead of 22) can reduce power consumption of your A/C by up to 15%.

Please note that depending on the conditions the Inverter Air Conditioner usually lowers capacity and increases capacity as required (much like a car accelerator) to automatically maintain indoor set temperatures. Therefore, will not run at maximum capacity at all times.

Want to know more about DUCTED SYSTEMS?

There are two main setups for ducted systems;

Basic Zoned Ducted Air Conditioning System; which is designed to condition **EITHER** Day (Living, Dining, Kitchen, Study) **OR** Night (Bed 1, Bed 2, Bed 3) for example. A Basic zoned ducted system is the most common method of designing a ducted air conditioning system, however, if you want to run the **whole house all of the time** then a **larger** system may be required, which could still be zoned, or run the whole of house at once.

CONSIDERATIONS.

A **ducted** system should be able to provide adequate comfort to at least **EITHER** the Day **OR** Night area (or zone) during normal ambient conditions provided that;

- External doors and windows are **shut** while Air Conditioning is operated and blinds/curtains are drawn to minimise heat from direct sunlight in summer, and heat losses in winter.
- The Air Conditioning is switched on early enough on a hot day say 8 - 9 am to prevent the internal space **reaching excessive temperatures** and therefore becoming much more difficult and costly to cool down.
- Doors to the non-air-conditioned areas should remain closed when not in use to prevent warm (or cold) air impacting the Air-Conditioned space.
- With a basic zoned ducted A/C system, in SUMMER once the peak heat of the day has passed, for example (early evening) and the main day area has already been cooled, then the bedrooms could also be run to pre-cool them prior to switching the system over fully to night zones. With a larger system, this is less of a consideration.

Although the **Wall Split System** can only condition the room or open area it is in, the same recommendations apply in relation to closing doors, windows, and drawing blinds etc. to minimise heat gain or loss in the conditioned space.

Maintenance: Do you service your car? Air Conditioning maintenance will ensure the best performance, longevity, and lowest running costs. Fortunately, A/C does not need a lot of maintenance, regular filter checks and clean every month or so (you can do this yourself) as well as one full service a year by a professional A/C service provider, are recommended.

OPERATION OF AIR CONDITIONING. A suggested reasonable set point temperature on your Air Conditioning is 22-23 degrees Celsius in summer (for Cooling) and 21-22 Degrees Celsius in winter (for Heating).

Temperature improvement **inside** the Air-Conditioned space over **outside** conditions is normally around 10-15 degrees improvement. For example; on a **32-degree summers day** (outside temperature) you could expect to achieve a very comfortable **22 degrees (inside temperature)**.

On a **cold winters day of say 12 degrees** outside, you could expect to achieve a cosy **22 degrees inside!**

HOME INSULATION.

In the same way we keep drinks cool in summer by putting them in an (insulated) Esky; or keep ourselves warm on a Winter's night with a Doona (which is also a form of insulation) providing additional insulation to your home may be beneficial to Air Conditioning effectiveness and lowering running costs.

If you do not already have it, then the addition of roof batts in the ceiling should further improve thermal efficiency of the home. This can greatly reduce heat leaking in thru the ceiling in summer, and warmth leaking out thru the ceiling in winter. Using a superior flexible duct in your system such as **Greenduct** also minimises energy loss.

There are a range of products including whirlybird and other types of fan driven roof ventilators which can be effective in reducing temperature inside the roofspace during summer (where the ducted Air Conditioning system and connective flexible ductwork is located). A reduction of the temperature in the roof space reduces the thermal stress on a ducted Air Conditioning unit, connective flex duct, and components.

For example, the temperature in the roof space can be **25 degrees hotter** than outside ambient conditions.

For example, on a **35-degree** sunny day can equal **60+ degrees Celsius in the roof space!** The addition of roof ventilators and eaves vents by a qualified installer **can reduce the temperature in the roof** to within 5 degrees of outside temp. For example, 35 degrees day can equal only 40 degrees in roof space, a significant reduction from **60+ degrees!**

This all helps the ducted system to perform better, and more efficiently, especially on extreme days.

We hope this information has been helpful, if you have any questions, or we can help in any way, please feel free to contact us at Mackies on 02 65 522 377.

Maximise your Air Conditioning Efficiency: Hints and Tips

Stay comfy and save energy with these helpful hints and tips to **maximise the efficiency of your air conditioning system. Beat the heat or cold while keeping your energy bills in check!**

1: Maintenance and Airflow

Regular Maintenance: It is a good idea to schedule an annual maintenance for your air conditioning unit to ensure optimal performance, once a year is usually enough if you are also doing the below yourself.

Clean or replace filters regularly to maintain proper airflow and improve efficiency.

Unblock Vents: Ensure that vents and registers are not obstructed by furniture, curtains, or other objects. Clear airflow allows the cool or warm air to circulate freely throughout your space.

Seal Air Leaks: Inspect windows, doors, and any other potential sources of air leaks, ensure doors and windows are closed while operating the Air Conditioner. Use weatherstripping around external doors to seal gaps and prevent conditioned air from escaping.

2: Temperature Control

Consider lowering the set point temperature by just one degree on HEATING mode (e.g., from 21°C down to 20°C) or one degree upwards on COOLING mode (from say 22 up to 23 degrees). This simple adjustment of just one degree can lead to significant power savings, reducing A/C energy consumption by as much as 15%.

Utilise Programmable Thermostats: Automatically adjust the temperature and operating times based on your daily schedule. This prevents unnecessary cooling or heating when no one is home.

Ducted A/C with Zones: If possible, use zone controls to direct cooling or heating to specific areas of your home. Close zones in unused rooms to redirect the air where it's needed most.

3: Lifestyle and Usage

Utilise natural elements: In SUMMER take advantage of cooler evenings and mornings by opening windows and allowing fresh air to circulate. You can also use fans strategically positioned to enhance natural ventilation. Keep blinds, curtains, or shades closed during the hottest parts of the day to block out the sun's heat. In WINTER, open blinds to allow natural sunlight and warmth in to your home. This will reduce the strain on your air conditioner.

4: Energy-Saving Tips

Energy-Efficient Equipment: When purchasing or upgrading your air conditioning system, choose energy-efficient Inverter models with a high Seasonal Energy Efficiency Ratio (SEER) rating. This helps reduce energy consumption and lowers your electricity bills.

Smart Energy Usage: Some air conditioners are also equipped with an "Eco" function which uses various 'smart' technologies to reduce the Air Conditioners energy consumption.

Proper Insulation: Ensure your home is properly insulated to keep conditioned air in, and hot or cold air out. Insulate ceilings, and use quality flexible ductwork such as **Greenduct** to prevent energy loss, and maintain a comfortable indoor environment.

For more personalised advice on maximising Air Conditioning efficiency, or to schedule a maintenance service, please contact our team on 02 65522377.

Note: The tips provided are general suggestions. For specific recommendations tailored to your unique situation, please feel free to consult with one of our qualified Air Conditioning professionals.
